

Weight Loss

Weight loss, in the context of medicine, health, or physical fitness, refers to a reduction of the total body mass, by a mean loss of fluid, body fat (adipose tissue), or lean mass (namely bone mineral deposits, muscle, tendon, and other connective tissue). Weight loss can either occur unintentionally because of malnourishment or an underlying disease, or from a conscious effort to improve an actual or perceived overweight or obese state. "Unexplained" weight loss that is not caused by reduction in calorific intake or exercise is called cachexia and may be a symptom of a serious medical condition.

Health Effects of Losing Weight Continuously

Some guidelines recommend dieting to lose weight for people with weight-related health problems, but not for otherwise healthy people. One survey found that almost half of all American adults attempt to lose weight through dieting, including 66.7% of obese adults and 26.5% of normal weight or underweight adults. Dieters who are overweight (but not obese), who are normal weight, or who are underweight may have an increased mortality rate as a result of dieting.

Health Benefits

You don't have to lose hundreds of pounds to enjoy the physical health benefits of weight loss. If you are currently overweight or obese, you may be able to lose just a small amount of weight to improve your overall health. In fact, some studies show that just a 5% to 10% decrease in your weight can affect your health. Losing weight can mean:

- Decreased joint pain
- Decreased risk of certain cancers
- Decreased risk of diabetes
- Decreased risk of heart disease
- Decreased risk of stroke
- Decreased risk or improvement in symptoms of osteoarthritis
- Decreased risk or improvement in symptoms of sleep apnea
- Improved blood sugar levels
- Improved cholesterol levels
- Improved mobility
- Lowered blood pressure
- Reduced back pain

Understand the Science Behind Weight Loss

Weight loss and gain revolve around caloric consumption and expenditure. Simply put, you lose weight when you consume fewer calories than you expend and you gain weight when you consume more calories than you sweat.

To drop those extra kilos, all you need to do is eat within your calorie budget and burn the required number of calories. So, a combination of the two works best suggested experts.

A good weight loss meal plan should follow some universal criteria:

- **Includes plenty of protein and fibre.** Protein- and fibre-rich foods help keep you fuller for longer, [reducing cravings](#) and helping you feel satisfied with smaller portions.
- **Limits processed foods and added sugar.** Rich in calories yet low in nutrients, these foods fail to stimulate fullness centres in your brain and make it difficult to lose weight or meet your nutrient needs.
- **Includes a variety of fruits and vegetables.** Both are rich in water and fibre, contributing to feelings of fullness. These nutrient-rich foods also make it easier to meet your daily nutrient requirements.
